

DISTRIBUTED ALGORITHMS

IMPLEMENTATION OF ELECTION IN ASYNCHRONOUS COMPLETE NETWORKS

by

João Almeida
Manuel Ribeiro

TESTS INTRODUCTION

To guarantee the quality of our implementation we ran multiple tests, a summary of those tests is present in Table 1. To ensure the algorithm was implemented correctly, information regarding the state of the processes was printed during the execution of the algorithm. All these tests are explained in the section *Detailed Tests*.

For each test we measured a series of parameters to evaluate the output of the algorithm. The parameters are:

- **Number of Level Increases:** Sum of the *Levels* of all processes at the end of execution.
- **Number of Captures:** Number of *Captures* that were successful, measured by the ordinary processes.
- **Number of Kill messages:** Number of messages sent by ordinary processes to *Kill* their previous owner.
- **Number of Acknowledgment messages:** Number of *Acknowledgment* messages sent for each *kill* or *Capture* messages.
- **Number of Capture/Level Discrepancies:** The difference between the number of *Captures* and number of *Level Increases*.

Test #	# Machines	Total # Processes	#Level increases	# Captures	# Kills	# Acks	# Messages	#Capture/Level Discrepancies
1	1	2	1	1	0	1	2	0
2	1	5	4	4	0	4	8	0
3	2	10	17	17	7	24		0
4	1	10	13	13	3	16	33	0
5	1	20	30	30	10	40	93	0
6	1	50	65	65	15	79	163	1
7	1	100	151	151	51	199	423	3
8	1	250	421	421	171	589	1396	3
9	1	500	773	773	274	1040	2375	7
10	1	750	1354	1354	604	1947	4556	11

Table 1: Tests summary

As you can see there is a difference between the number of *Captures* and the *Level Increases*, for the larger tests. Theoretically these should be the same, however due to a known problem of synchronization, some of these captures do not result in a level increase for the candidate because it is killed before receiving the acknowledgment. This acknowledgment arrives later, however it is ignored, as the candidate is already dead. So this way the number of acknowledgments respects: $\#ACKS = \#KILLS + \#CAPTURES - \#DISCREPANCIES$.

DETAILED TESTS

```

Test 1 output
[INFO] Connections Ready
[Process: 1] [C] Is now a Candidate.
[Process: 2] [O] Captured by Candidate Process: 1.
[Process: 1] [C] Elected!!
[Process: 1] [C] Level = 2. Times Captured = 0. Acks = 1.
[Process: 2] [C] Level = 1. Times Captured = 1. Acks = 0.
[INFO]
Level Sum - Number of Processes = 1.
Captures Sum = 1
Total Kills = 0
Total Acks = 1
Missed captures: 0

```

In this example, *Test 1*, two processes are trying to get elected. Process 1 is the first candidate and captures Process 2 immediately, making itself the elected process. The '*Level Sum - Number of Processes*' is equal to the '*Captures Sum*', which proves the correctness of the algorithm for two processes.

```

Test 4 output
[INFO] Connections Ready
[Process: 9] [C] Is now a Candidate.
[Process: 1] [C] Is now a Candidate.
[Process: 7] [C] Is now a Candidate.
[Process: 5] [C] Is now a Candidate.
[Process: 4] [C] Is now a Candidate.
[Process: 2] [C] Is now a Candidate.
[Process: 8] [C] Is now a Candidate.
[Process: 3] [C] Is now a Candidate.
[Process: 10] [C] Is now a Candidate.
[Process: 6] [C] Is now a Candidate.
[Process: 5] [O] Captured by Candidate Process: 4.
[Process: 8] [O] Captured by Candidate Process: 1.
[Process: 9] [O] Captured by Candidate Process: 2.
[Process: 2] [O] Captured by Candidate Process: 5.
[Process: 4] [O] Captured by Candidate Process: 9.
[Process: 6] [O] Captured by Candidate Process: 7.
[Process: 3] [O] Captured by Candidate Process: 4.
[Process: 10] [O] Captured by Candidate Process: 7.
[Process: 1] [O] Captured by Candidate Process: 2.
[Process: 1] [C] Was Killed
[Process: 1] [C] Received a kill Message, but was already killed.
[Process: 8] [O] Captured by Candidate Process: 7.
[Process: 1] [C] Received a kill Message, but was already killed.
[Process: 1] [O] Captured by Candidate Process: 7.
[Process: 2] [C] Was Killed
[Process: 5] [O] Captured by Candidate Process: 7.
[Process: 4] [C] Was Killed
[Process: 2] [O] Captured by Candidate Process: 7.
[Process: 5] [C] Was Killed
[Process: 9] [O] Captured by Candidate Process: 7.
[Process: 2] [C] Received a kill Message, but was already killed.
[Process: 4] [O] Captured by Candidate Process: 7.
[Process: 9] [C] Was Killed
[Process: 3] [O] Captured by Candidate Process: 7.

```

```

[Process: 4]      [C]      Received a kill Message, but was already killed.
[Process: 7]      [C]      Elected!!
[Process: 1]      [C]      Level = 2. Times Captured = 2. Acks = 4.
[Process: 2]      [C]      Level = 3. Times Captured = 2. Acks = 4.
[Process: 3]      [C]      Level = 1. Times Captured = 2. Acks = 0.
[Process: 4]      [C]      Level = 3. Times Captured = 2. Acks = 4.
[Process: 5]      [C]      Level = 2. Times Captured = 2. Acks = 2.
[Process: 6]      [C]      Level = 1. Times Captured = 1. Acks = 0.
[Process: 7]      [C]      Level = 10. Times Captured = 0. Acks = 9.
[Process: 8]      [C]      Level = 1. Times Captured = 2. Acks = 0.
[Process: 9]      [C]      Level = 2. Times Captured = 2. Acks = 2.
[Process: 10]     [C]      Level = 1. Times Captured = 1. Acks = 0.
[INFO]
Level Sum - Number of Processes = 16
Captures Sum = 16
Total Kills = 9
Total Acks = 25
Missed captures: 0

```

With this example from *Test 4* we want to prove that even if all candidates start the election at the same time, the algorithm still works as expected.

Test 6 output

```

CONCLUSION

Our implementation worked exactly as expected on small and medium size tests, on larger tests, more than 50 processes, the algorithm still elected correctly and the number of
